THE HUMAN BRAIN

L. Eetors, Avenue de Cortenberg, 1040 Bruxelles, (Belgium)

Man takes up consciouness of himself and of his environment by modulating the speed of the afferent impulses. So he realises discrimination in space, discrimination in time, localisation and orientation without use of a clock a map a compass and a coded registration with feed back. Acceleration brings up discrimination in space, slowing down brings up discrimination in time, temporal dispersion brings up localisation and inversion of speed brings up orientation. Practice, molecular polishing and enzyme formation builds up learning. Man takes up consciouness during active sensory motor dialogue in a reverberating circuit. The human brain reaches its structure and gests its organisation throught its activity during the relation of contact with the environment. We propose a new definition for the human brain and for cybernetics: intelligence by modulation in the nerves system of the speed of afferent impulses and not by informatics, coded registration and feed back.
